Canonical Characteristic Sets of Characterizable Differential Ideals

February 2, 2008

Abstract We study the concept of *canonical characteristic set* of a characterizable differential ideal. We propose an efficient algorithm that transforms any characteristic set into the canonical one. We prove the basic properties of canonical characteristic sets. In particular, we show that in the ordinary case for any ranking the order of each element of the canonical characteristic set of a characterizable differential ideal is bounded by the order of the ideal. Finally, we propose a factorization-free algorithm for computing the canonical characteristic set of a characterizable differential ideal represented as a radical ideal by a set of generators. The algorithm is not restricted to the ordinary case and is applicable for an arbitrary ranking.

1 Introduction

Characterizable ideals have been introduced by Hubert (13) and play a central role in the constructive theory of radical differential ideals. On the one hand, characterizable ideals can be specified by their characteristic sets and this representation allows to solve important computational problems such as ideal membership. On the other hand, there exist factorization-free algorithms that decompose any radical differential ideal specified by a system of generators into an intersection of characterizable ideals represented by their characteristic sets, which allows to reduce computational problems for radical ideals to characterizable ones.

Unlike reduced Gröbner bases of algebraic ideals, characteristic sets of (differential) ideals are not unique. The problem of constructing a unique, or canonical, representation was first addressed in (3) in the case of regular differential ideals, for which the concept of characteristic presentation (which is almost a characteristic set) is defined. It is shown that, whenever a regular differential ideal has a characteristic presentation, it is unique.

In (13), the concept of characteristic presentation is replaced by that of a characterizing set of a characterizable differential ideal, and an algorithm for computing such a set is proposed. Further development and generalization to triangular sets appeared in (14; 15). The efficiency of the mentioned algorithm was improved in (16).

Finally, in (4), an additional requirement on characterizing sets is imposed: the initials of the polynomials in the characteristic set are required to be independent of the leaders and the polynomials themselves to be primitive over the ring of polynomials in non-leaders. It is shown that, for characterizable ideals, the characteristic set satisfying this requirement is unique up to multiplication by elements of the basic field. In the algebraic case, a triangular set satisfying the above requirement is called a reduced Gröbner chain (14), and it is shown in (14, Proposition 5.17) that every algebraic characterizable ideal admits a unique characteristic set that is a reduced Gröbner chain. By applying (15, Theorem 5.5), this result can be trivially lifted to differential characterizable ideals.

We give afresh a detailed constructive proof of existence and uniqueness of the canonical characteristic set of a characterizable differential ideal. Based on the algorithm for inverting the polynomials w.r.t. a characteristic set (6), we propose an algorithm (Algorithm 2) that, given any characteristic set that characterizes an ideal, constructs the canonical characterizing set. These results are contained in Sections 3 and 5.

The canonical characteristic set is a convenient tool for testing equality of characterizable differential ideals. Indeed, two characterizable ideals coincide iff their canonical characteristic sets coincide. This method is used in (10) in order to make a certain characteristic decomposition irredundant. On

the other hand, equality of prime differential ideals can be tested using the method described in (17, Exercise 1, page 171). As we show in Section 8, this method is also applicable to characterizable ideals.

We study the essential properties of canonical characteristic sets (see Propositions 2, 4, and 5). In particular, we prove that the partial derivatives of the polynomials in the canonical characteristic sets w.r.t. any differential indeterminate do not belong to the ideal. Although these properties look algebraic, we also bring some differential flavor into their study. We also describe the structure of all characteristic sets whose initials do not depend on leaders (Corollary 1).

The main results of the paper are the following. First, we show that *in the ordinary case for any ranking and a prime differential ideal there exists a characteristic set with bounded in advance orders of its elements* (Theorem 6). Our result generalizes (22, Theorem 24), which was proved there for *elimination rankings only*. Then we obtain a similar result for *characterizable differential ideals* (see Theorem 7) without any restrictions to rankings. In Section 5 we show how to apply this result. In Theorem 8 we obtain a *bound on the orders of the elements in the canonical characteristic set* of a characterizable differential ideal.

Considering prime differential ideals as a particular case of characterizable ones, in Example 2 we show that Sadik's property of irreducibility (22) does not necessarily hold for the canonical characteristic set. This property is very important for the proof of Theorem 6 together with another natural property giving a characteristic set of a prime differential ideal with a predicted bound for the order of its elements.

As it is demonstrated in (5), it is possible to convert characteristic sets of prime differential ideals from one ranking to another efficiently. Furthermore, an efficient Monte-Carlo algorithm for converting characteristic sets of prime algebraic ideals has been developed in (11). This algorithm can be applied in case of prime ordinary differential ideals using the reduction of this case to the algebraic one carried out in (12); the reduction essentially involves the concept of canonical characteristic set and its properties.

Finally, we propose an algorithm for computing the canonical characteristic set of a characterizable differential ideal from a set of its generators (Algorithm 3). Examples in Section 9 illustrate our algorithms, as well as justify why the requirement of characterizability cannot be relaxed to that of radicality.

2 Preliminaries

2.1 Basic definitions

Differential algebra studies systems of polynomial partial differential equations from the algebraic point of view. The approach is based on the concept of differential ring introduced by Ritt. Recent tutorials on the constructive theory of differential ideals are presented in (15; 24). We also use the Gröbner bases technique (7; 1). A differential ring is a commutative ring with unity endowed with a set of differentiations $\Delta = \{\delta_1, \dots, \delta_n\}$. The case of $\Delta = \{\delta\}$

is called *ordinary*. If R is an ordinary differential ring and $y \in R$, we denote $\delta^k y$ by $y^{(k)}$.

Construct the multiplicative monoid $\Theta = (\delta_1^{k_1} \delta_2^{k_2} \cdots \delta_n^{k_n}, k_i \geq 0)$. The ring of *differential polynomials* in l differential indeterminates over a differential field k is a ring of commutative polynomials with coefficients in k in the infinite set of variables $\{\theta y_i, 1 \leq i \leq l\}$ (see (17; 18; 21)). Derivatives from Θ act on variables as $\theta_1(\theta_2 y_i) = (\theta_1 \theta_2) y_i$ for all $\theta_1, \theta_2 \in \Theta$ and $1 \leq i \leq l$. The ring of differential polynomials is denoted by $k\{y_1, \dots, y_l\}$ or $k\{Y\}$, where $Y = \{y_1, \dots, y_l\}$ is the set of differential indeterminates. We consider the case of $\text{char } k = 0$ only. We denote polynomials by $f, g, h, \dots$ and use letters I, J, P for ideals.

Let $F \subset k\{y_1, \dots, y_l\}$ be a set of differential polynomials. For the differential and radical differential ideal generated by F in $k\{y_1, \dots, y_l\}$, we use notations $[F]$ and $\{F\}$, respectively. A prime differential ideal containing radical differential ideal $\{F\}$ is called a prime component of $\{F\}$. A prime component is called *essential*, if it is not contained in any other prime component of $\{F\}$. According to (21, Section I.16), every radical differential ideal has finitely many essential prime components and is equal to their intersection. Moreover, any finite prime decomposition of $\{F\}$ contains all its essential components.

We need the notion of reduction for algorithmic computations. First, we introduce a *ranking* on the set of differential variables of $k\{y_1, \dots, y_l\}$. A ranking is a total ordering on the set $\{\theta y_i\}$, where $\theta \in \Theta$ and $1 \leq i \leq l$, satisfying the following conditions:

1. $\theta u \geq u$,
2. $u \geq v \implies \theta u \geq \theta v$.

Let u be a differential variable in $k\{y_1, \dots, y_l\}$, that is, $u = \theta y_j$ for a differential operator $\theta = \delta_1^{k_1} \delta_2^{k_2} \cdots \delta_n^{k_n} \in \Theta$ and $1 \leq j \leq l$. The *order* of u is defined as $\text{ord } u = \text{ord } \theta = k_1 + \dots + k_n$. If f is a differential polynomial then $\text{ord } f$ denotes the maximal order of differential variables appearing effectively in f . A ranking $>$ is said to be *orderly* iff $\text{ord } u > \text{ord } v$ implies $u > v$ for all differential variables u and v . A ranking $>_{el}$ is called an *elimination* ranking iff $y_i >_{el} y_j$ implies $\theta_1 y_i >_{el} \theta_2 y_j$ for all $\theta_1, \theta_2 \in \Theta$.

Let a ranking $<$ be fixed. The differential variable θy_j of the highest rank appearing in a differential polynomial $f \in k\{y_1, \dots, y_l\} \setminus k$ is called the *leader* of f . We denote the leader by u_f . Represent f as a univariate polynomial in u_f :

$$f = I_f u_f^n + a_1 u_f^{n-1} + \dots + a_n.$$

The polynomial I_f is called the *initial* of f .

Apply any $\delta \in \Delta$ to f :

$$\delta f = \frac{\partial f}{\partial u_f} \delta u_f + \delta I_f u_f^n + \delta a_1 u_f^{n-1} + \dots + \delta a_n.$$

The leading variable of δf is δu_f and the initial of δf is called the *separant* of f , denoted S_f . Note that for all $\theta \in \Theta$, $\theta \neq 1$, the initial of θf is equal to S_f . The differential monomial u_f^n is called the *rank* of f and denoted $\text{rank } f$.

Extend the ranking relation on differential variables to ranks: $u_1^{d_1} > u_2^{d_2}$ iff either $u_1 > u_2$ or $u_1 = u_2$ and $d_1 > d_2$. Also, a ranking $>$ on differential variables induces a lexicographic ordering $>_{\text{lex}}$ on their power products. This ordering can be extended to a partial ordering on differential polynomials, which we denote by $>_{\text{lex}}$ as well.

We say that a differential polynomial f is *partially reduced* w.r.t. g iff no proper derivative of u_g appears in f . A differential polynomial f is *reduced* w.r.t. a differential polynomial g iff f is partially reduced w.r.t. g and $\deg_{u_g} f < \deg_{u_g} g$. Consider any subset $\mathbb{A} \subset k\{y_1, \dots, y_l\} \setminus k$. We say that $\mathbb{A}$ is *autoreduced* iff each element of $\mathbb{A}$ is reduced w.r.t. all the others. Every autoreduced set is finite (17, Chapter I, Section 9). For autoreduced sets we use capital letters $\mathbb{A}, \mathbb{B}, \mathbb{C}, \dots$ and notation $\mathbb{A} = A_1, \dots, A_p$ to specify the list of the elements of $\mathbb{A}$ arranged in order of increasing rank.

We denote the product of the initials and the separants of the elements of $\mathbb{A}$ by $I_{\mathbb{A}}$ and $S_{\mathbb{A}}$, respectively. Denote $I_{\mathbb{A}} \cdot S_{\mathbb{A}}$ by $H_{\mathbb{A}}$. Let S be a finite set of differential polynomials. Denote by S^∞ the multiplicative set containing 1 and generated by S . Let I be an ideal in a commutative ring R . The *saturated ideal* $I : S^\infty$ is defined as $\{a \in R \mid \exists s \in S^\infty : sa \in I\}$. If I is a differential ideal then $I : S^\infty$ is also a differential ideal (see (17; 21; 18; 24)).

Consider two differential polynomials f and g in $R = k\{y_1, \dots, y_l\}$. Let I be the differential ideal in R generated by g . Applying a finite number of differentiations and pseudo-divisions (multiplying by initials and separants together with differentiations and algebraic reductions) one can compute a *differential partial remainder* f_1 and a *differential remainder* f_2 of f w.r.t. g such that there exist $s \in S_g^\infty$ and $h \in H_g^\infty$ satisfying $sf \equiv f_1$ and $hf \equiv f_2 \pmod{I}$ with f_1 and f_2 partially reduced and reduced w.r.t. g , respectively (see (13) for definitions and the algorithm for computing remainders).

Let $\mathbb{A}$ be an autoreduced set in $k\{y_1, \dots, y_l\}$. Consider the polynomial ring $k[x_1, \dots, x_n]$ with $x_1, \dots, x_n$ belonging to ΘY for $Y = y_1, \dots, y_l$. Let $L, N \subset \{x_1, \dots, x_n\}$ be the sets of “leaders” and “non-leaders” appearing in the autoreduced set $\mathbb{A}$, respectively. We denote $k[x_1, \dots, x_n]$ by $k[N][L]$ and the leader of A_i by u_{A_i} or u_i for each $1 \leq i \leq p$. In what follows, we will often consider elements of $\mathbb{A}$ as polynomials in leaders with coefficients being polynomials in non-leaders.

Let $\mathbb{A} = A_1, \dots, A_r$ and $\mathbb{B} = B_1, \dots, B_s$ be autoreduced sets. We say that $\mathbb{A}$ has lower rank than $\mathbb{B}$ iff there exists $k \leq r, s$ such that $\text{rank } A_i = \text{rank } B_i$ for $1 \leq i < k$ and $\text{rank } A_k < \text{rank } B_k$, or if $r > s$ and $\text{rank } A_i = \text{rank } B_i$ for $1 \leq i \leq s$. We say that $\text{rank } \mathbb{A} = \text{rank } \mathbb{B}$ iff $r = s$ and $\text{rank } A_i = \text{rank } B_i$ for $1 \leq i \leq r$.

The following notion of a characteristic set in *Kolchin’s sense* in characteristic zero is crucial in our further discussions. It was first introduced by Ritt for prime differential ideals, and then extended by Kolchin to arbitrary differential ideals.

Definition 1 (17, page 82) An autoreduced set of the lowest rank in an ideal I is called a *characteristic set* of I .

We call these sets *Kolchin characteristic sets* to avoid confusion with other notions, e.g., in (13; 15) characteristic sets are used in Kolchin’s sense and in some other senses.

As it is mentioned in (17, Lemma 8, page 82), in the case of $\text{char } k = 0$, a set $\mathbb{A}$ is a characteristic set of a proper differential ideal I iff each element of I reduces to zero w.r.t. $\mathbb{A}$. Moreover, the leaders and the correspondent degrees of these leaders of any two characteristic sets of I coincide.

Let v be a derivative in $k\{y_1, \dots, y_l\}$. Denote by $\mathbb{A}_v$ the set of the elements of $\mathbb{A}$ and their derivatives of rank strictly lower than v .

Definition 2 (17, III.8) An autoreduced set $\mathbb{A}$ is called *coherent* if whenever $A, B \in \mathbb{A}$ are such that u_A and u_B have a common derivative $v = \psi u_A = \phi u_B$, then $S_B \psi A - S_A \phi B \in (\mathbb{A}_v) : H_{\mathbb{A}}^\infty$.

Any characteristic set of a differential ideal is coherent (see (17; 21; 18; 24)).

Definition 3 (13, Definition 2.6) A differential ideal I in $k\{y_1, \dots, y_l\}$ is said to be *characterizable* if there exists a characteristic set $\mathbb{A}$ of I in Kolchin's sense such that $I = [\mathbb{A}] : H_{\mathbb{A}}^\infty$. We call any such characteristic set $\mathbb{A}$ a *characterizing* set of I .

Characterizable ideals are radical (13, Theorem 4.4).

Let $\mathbb{A}$ be an autoreduced set in $k\{y_1, \dots, y_l\} = k\{Y\}$, and let $k[N][L]$ be the polynomial ring associated with $\mathbb{A}$, where L is the set of leaders of polynomials in $\mathbb{A}$ and N is the set of non-leaders, i.e., $N = \Theta Y \setminus \Theta L$. Note that the set N can be infinite when $\Delta \neq \emptyset$.

Definition 4 (6, Definition 1.2.1) Let f be a polynomial in $k[N][L]$. We say that f is *invertible* w.r.t. $\mathbb{A}$ iff f is invertible modulo $(\mathbb{A})$ in $k(N)[L]$, i.e., there exist $g \in k[N, L]$ and $h \neq 0$ in $k[N]$ such that $f \cdot g \equiv h \pmod{(\mathbb{A})}$.

We say that the initials of an autoreduced set $\mathbb{A} = A_1, \dots, A_p$ are *invertible* if I_{A_i} is invertible w.r.t. the autoreduced set $A_1, \dots, A_{i-1}$ for all i , $2 \leq i \leq p$. We also say that the separants of $\mathbb{A}$ are *invertible* if S_{A_i} is invertible w.r.t. the autoreduced set $A_1, \dots, A_i$ for all i , $1 \leq i \leq p$.

2.2 Important assertions

Consider several important results concerning radical differential ideals in rings of differential polynomials. The technique described in (13; 17) helps us to cover some properties of these ideals.

Theorem 1 (17, III.8, Lemma 5) Let $\mathbb{A}$ be a coherent autoreduced set in $k\{y_1, \dots, y_l\}$. Suppose that a differential polynomial g is partially reduced w.r.t. $\mathbb{A}$. Then $g \in [\mathbb{A}] : H_{\mathbb{A}}^\infty$ iff $g \in (\mathbb{A}) : H_{\mathbb{A}}^\infty$.

Note that Theorem 1 is also known as *Rosenfeld's lemma*.

Theorem 2 (13, Theorem 3.2) Let $\mathbb{A}$ be an autoreduced set of $k[N][L]$. If $1 \notin (\mathbb{A}) : H_{\mathbb{A}}^\infty$ then any minimal prime of $(\mathbb{A}) : H_{\mathbb{A}}^\infty$ admits the set of non-leaders of $\mathbb{A}$, N , as a transcendence basis. More specially, any characteristic set of a minimal prime of $(\mathbb{A}) : H_{\mathbb{A}}^\infty$ has the same set of leaders as $\mathbb{A}$.

Theorem 3 (13, Theorem 4.5) *Let $\mathbb{A}$ be a coherent autoreduced set of $R = k\{y_1, \dots, y_l\}$ such that $1 \notin [\mathbb{A}] : H_{\mathbb{A}}^{\infty}$. There is a one-to-one correspondence between the minimal primes of $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ in $k[N][L]$ and the essential prime components of $[\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ in R . Assume $\mathbb{C}_i$ is a characteristic set of a minimal prime of $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$. Then $\mathbb{C}_i$ is the characteristic set of a single essential prime component of $[\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ (and vice versa).*

Theorem 4 (6, Theorem 1.2.2) *An autoreduced set $\mathbb{A} = A_1, \dots, A_p$ is a characteristic set of the algebraic ideal $(\mathbb{A}) : I_{\mathbb{A}}^{\infty}$ in $k[N, L]$ iff the initials I_{A_i} are invertible for all $2 \leq i \leq p$.*

Theorem 5 (6, Theorem 2.1.1) *A coherent autoreduced set $\mathbb{A} = A_1, \dots, A_p$ is a characteristic set of the ideal $[\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ iff the initials I_{A_i} and S_{A_j} are invertible for all $2 \leq i \leq p$, $1 \leq j \leq p$.*

Lemma 1 *Let $\mathbb{A} = A_1, \dots, A_p$ be an autoreduced set in the ring $k[x_1, \dots, x_m] = R$ and a characteristic set of $(\mathbb{A}) : I_{\mathbb{A}}^{\infty}$. Suppose that a polynomial $f = a_m x_t^m + \dots + a_0 \in R$ is reducible to zero w.r.t. $\mathbb{A}$ and the indeterminate x_t does not appear in A_i for each $1 \leq i \leq p$. Then a_j is reducible to zero w.r.t. $\mathbb{A}$ for all $0 \leq j \leq m$.*

Proof Since f is reducible to zero w.r.t. $\mathbb{A}$, there exists $I \in I_{\mathbb{A}}^{\infty}$ such that

$$I \cdot f = \sum_{i=1}^p g_i A_i.$$

Let $g_i = \sum_{j=1}^{t_i} h_{ij} x_t^j$ for each $1 \leq i \leq p$. Thus, we have $I \cdot \sum_{k=0}^m a_k x_t^k = \sum_{k=0}^q d_k x_t^k$ with $d_k \in (\mathbb{A})$. Hence, $I \cdot a_i \in (\mathbb{A})$ for each $1 \leq i \leq m$, that is, $a_i \in (\mathbb{A}) : I_{\mathbb{A}}^{\infty}$. Since $\mathbb{A}$ is a characteristic set of $(\mathbb{A}) : I_{\mathbb{A}}^{\infty}$, we have that all a_i are reducible to zero w.r.t. $\mathbb{A}$.

We note an important property of a characteristic set of an arbitrary differential ideal.

Proposition 1 *Let I be a differential ideal with two characteristic sets $\mathbb{A} = A_1, \dots, A_p$ and $\mathbb{C} = C_1, \dots, C_p$. If the initials of both $\mathbb{A}$ and $\mathbb{C}$ do not depend on the leaders then*

$$I_{A_i} C_i = I_{C_i} A_i$$

for all i , $1 \leq i \leq p$.

Proof Let

$$A_i = I_{A_i} u_{A_i}^{n_i} + a_{i,1} u_{A_i}^{n_i-1} + \dots + a_{i,n_i},$$

$$C_i = I_{C_i} u_{A_i}^{n_i} + c_{i,1} u_{A_i}^{n_i-1} + \dots + c_{i,n_i},$$

where u_{A_i} is the leader of both A_i and C_i , $1 \leq i \leq p$. We have

$$f_i := I_{A_i} C_i - I_{C_i} A_i = \sum_{j=1}^{n_i} (c_{i,j} I_{A_i} - a_{i,j} I_{C_i}) u_{A_i}^{n_i-j} \in I.$$

By Theorem 4 we have $\mathbb{A}$ is a characteristic set of the ideal I . Hence, the polynomial f_i is reducible to zero w.r.t. $\mathbb{A}$. The initials of $\mathbb{A}$ do not depend on leaders, hence $\mathbb{A}$ is a characteristic set of $(\mathbb{A}) : I_{\mathbb{A}}^{\infty}$ by Theorem 4. The variable u_{A_i} does not appear in $A_1, \dots, A_{i-1}$.

Hence, by Lemma 1 the coefficients of f_i w.r.t. u_{A_i} are reducible to zero w.r.t. $\mathbb{A}$. But the initials of both $\mathbb{A}$ and $\mathbb{C}$ do not depend on the leaders, hence the powers of leaders in the coefficients of f_i are less than or equal to the powers of the corresponding leaders of $A_1, \dots, A_{i-1}$ and no reduction can go. So, we obtain that $c_{i,j}I_{A_i} = a_{i,j}I_{C_i}$, $1 \leq j \leq n_i$, $1 \leq i \leq p$. Thus, $f_i = 0$ for all i , $1 \leq i \leq p$.

3 Canonical characteristic sets

3.1 Definition and computation

Let a differential ranking be *fixed*. The following definition is a summary of (4, Section 2.2.6).

Definition 5 A characteristic set $\mathbb{C} = C_1, \dots, C_p$ of a characterizable differential ideal I is called *canonical* if the following conditions are satisfied:

1. the initial I_{C_i} depends only on non-leaders N of $\mathbb{C}$ for all i , $1 \leq i \leq p$;
2. for each i , $1 \leq i \leq p$,
 - the polynomial C_i has no factors in $k[N]$;
 - the leading coefficient of the leading monomial of I_{C_i} w.r.t. the induced lexicographic ordering $>_{\text{lex}}$ on monomials from $k[N]$ is equal to 1.

Note that, unlike (4), we do not require in the definition that $\mathbb{C}$ characterizes I , but we will show in Proposition 2 that this is the case. We have also replaced the set $N_{\mathbb{C}}$ of non-leaders effectively occurring in $\mathbb{C}$ by the set $N = \Theta Y \setminus \Theta L$ of all non-leaders (where L is the set of leaders of $\mathbb{C}$). Clearly, this replacement yields an equivalent definition, which is more convenient for us, because it provides a ring $k(N)[L]$ independently of the choice of the characteristic set $\mathbb{C}$, while the field of coefficients $k(N_{\mathbb{C}})$ of the polynomial ring $k(N_{\mathbb{C}})[L]$ depends on $\mathbb{C}$.¹ Other than this detail, the construction of the canonical characteristic set follows from (14, Section 5.4) and (15, Theorem 5.5).

The following algorithm is a combination of (13, Algorithm 3.8) and (13, Algorithm 7.1) restricted to characterizable ideals. Its correctness is justified in Proposition 2 and implies the existence of the canonical characteristic set. The uniqueness of the canonical characteristic set essentially follows from (4, Theorem 3), yet, since we have slightly changed the definition, we provide another proof of uniqueness.

Note that in the above algorithm the Gröbner basis is computed for a system of polynomials over the field of fractions $k(N)$, where N is an infinite

¹ The idea of constructing a canonical field of coefficients by considering the infinite set of all non-leading derivatives was communicated to the first author by E. Hubert.

Algorithm 1 Canonical Characteristic Set

INPUT: a characterizing set $\mathbb{A}$ of a characterizable differential ideal $I = [\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ in $k\{y_1, \dots, y_t\} = k\{Y\}$.

OUTPUT: the canonical characteristic set of I .

- $L := \text{Leaders}(\mathbb{A})$.
- $N := \Theta Y \setminus \Theta L$.
- $GB := \text{Reduced_Gröbner_Basis}((\mathbb{A}) : H_{\mathbb{A}}^{\infty})$ in $k(N)[L]$ w.r.t. $>_{\text{lex}}$.
- $\mathbb{C} := \text{Clear_out_denominators}(GB)$ in $k(N)[L]$.
- divide each element of $\mathbb{C}$ by its leading coefficient from k
- Return $\mathbb{C}$.

set. This does not raise any problems with computability, since the input consists of polynomials over $k(N_{\mathbb{A}})$, where $N_{\mathbb{A}}$ is a finite subset of non-leading derivatives effectively present in $\mathbb{A}$. Since the Gröbner basis computation does not lead out of the field of definition of the input polynomials, one can say that, for the given system $\mathbb{A}$, the computation of the Gröbner basis of the ideal $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ in $k(N)[L]$ is equivalent to that in $k(N_{\mathbb{A}})[L]$. The same applies to clearing out the denominators in the Gröbner basis in $k(N)[L]$, i.e., effectively this procedure is performed in $k(N_{\mathbb{A}})[L]$.

Proposition 2 *Algorithm 1 computes a canonical characteristic set of the characterizable differential ideal I . Moreover, this characteristic set characterizes I .*

Proof Since ideal $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ is characterizable and according to (13, Remark after Lemma 3.9), the reduced Gröbner basis GB has $|L|$ elements and characterizes $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ in $k(N)[L]$. Thus, $(\mathbb{A}) : H_{\mathbb{A}}^{\infty} = (GB)$ is a zero-dimensional irredundant characteristic decomposition of $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ in $k(N)[L]$ consisting of the single component (GB) . Now, according to (13, Theorem 3.10), $(\mathbb{C}) : I_{\mathbb{C}}^{\infty}$ is a single-component characteristic irredundant decomposition of $(\mathbb{A}) : H_{\mathbb{A}}^{\infty}$ in $k[N][L]$, and by (13, Theorem 6.2)

$$I = [\mathbb{A}] : H_{\mathbb{A}}^{\infty} = [\mathbb{C}] : H_{\mathbb{C}}^{\infty}$$

is a single-component characteristic irredundant decomposition of I in $k\{Y\}$. The latter, in particular, implies that $\mathbb{C}$ characterizes I .

To clear out denominators means to multiply each $C_i \in GB$ by the least common multiple q of the denominators of its coefficients. Here each $C_i = u^t + \frac{\alpha_{t-1}}{\beta_{t-1}}u^{t-1} + \dots + \frac{\alpha_0}{\beta_0}$ is considered as a univariate polynomial in its leader u , and its coefficients $\frac{\alpha_i}{\beta_i}$, $i = 0, \dots, t-1$ are assumed to be irreducible fractions over $k[N]$.

Now let $C'_i = qC_i$. The coefficients of C'_i are polynomials $q, \alpha_{t-1} \cdot \frac{q}{\beta_{t-1}}, \dots, \alpha_0 \cdot \frac{q}{\beta_0}$, whose greatest common divisor is 1. Indeed, let $\gamma_i = \frac{q}{\beta_i}$, and suppose that there exists an irreducible polynomial $d \in k[N] \setminus k$ such that $d|q$ and $d|\alpha_i\gamma_i$, $i = 0, \dots, t-1$. If for some j , $d \nmid \gamma_j$, then we have $d|\alpha_j$ and $d|\beta_j = \frac{q}{\gamma_j}$, which contradicts the irreducibility of the fraction $\frac{\alpha_j}{\beta_j}$. Hence, for all $j \in \{0, \dots, t-1\}$, $d|\gamma_j$, which implies that $\beta_j = \frac{q}{\gamma_j} \cdot \frac{q}{d}$. The latter contradicts the fact that $q = \text{lcm}(\beta_0, \dots, \beta_{t-1})$.

Thus, set $\mathbb{C}$ satisfies the requirements of Definition 5 (the leading coefficient in k can be easily canceled) and hence is the canonical characteristic set of I .

Proposition 3 *If $\mathbb{C}, \mathbb{D}$ are two characteristic sets of a characterizable differential ideal I satisfying the requirements of Definition 5, then $\mathbb{C} = \mathbb{D}$.*

Proof Let $I_1 = (\mathbb{C}) : H_{\mathbb{C}}^{\infty}$ and $I_2 = (\mathbb{D}) : H_{\mathbb{D}}^{\infty}$ be the saturated algebraic ideals specified by $\mathbb{C}$ and $\mathbb{D}$, respectively, considered in the ring $k[L \cup N]$.

By the Rosenfeld Lemma, $\mathbb{C} \subset I_2$ and $\mathbb{D} \subset I_1$.

Now consider the corresponding ideals $J_1 = (\mathbb{C}) : H_{\mathbb{C}}^{\infty}$ and $J_2 = (\mathbb{D}) : H_{\mathbb{D}}^{\infty}$ in $k(N)[L]$. Since the polynomials in $k[L \cup N]$ can be also considered as elements of $k(N)[L]$ and, hence, of $k(N)[L]$, we have $\mathbb{C} \subset J_2$ and $\mathbb{D} \subset J_1$. Since $I_{\mathbb{C}}$ and $I_{\mathbb{D}}$ belong to $k(N)$, ideals J_1 and J_2 are generated by $\mathbb{C}$ and $\mathbb{D}$, which implies the equality of these ideals. Denote $J = J_1 = J_2$.

Let $\bar{\mathbb{C}} = \{f/I_f \mid f \in \mathbb{C}\}$ and, similarly, define $\bar{\mathbb{D}}$. According to Definition 5, the initials of $\mathbb{C}$ and $\mathbb{D}$ depend only on non-leaders, hence $\bar{\mathbb{C}}$ and $\bar{\mathbb{D}}$ are sets of monic polynomials in $k(N)[L]$ generating the ideal J . Moreover, their sets of leading monomials w.r.t. the lexicographic ordering $<_{\text{lex}}$ on the monomials over L induced by the ranking are equal to $R = \text{rank } \mathbb{C} = \text{rank } \mathbb{D}$. Thus, $\bar{\mathbb{C}}$ and $\bar{\mathbb{D}}$ are reduced Gröbner bases of J , whence they must be equal.

Now the conditions of Definition 5 imply that $\mathbb{C} = \mathbb{D}$ as well.

Note that the equality of ideals I_1 and I_2 , and hence of the ideals J_1 and J_2 , in the above proof also follows from (3, Theorem 6.1). However, as we have seen, this equality becomes rather straightforward, once the polynomial ring $k(N)[L]$ is considered.

3.2 Basic properties

Corollary 1 *For a characterizable differential ideal, all characteristic sets with initials containing only non-leaders can be obtained from the canonical one through multiplying its elements by some polynomials from $k[N]$.*

Proof Let $\mathbb{A} = A_1, \dots, A_p$ be a characteristic set whose initials belong to $k[N]$. Consider set $\mathbb{A}' = A'_1, \dots, A'_p$, where $A'_i = \frac{A_i}{I_{A_i}} \in k(N)[L]$. Then the leading monomials of $\mathbb{A}'$ coincide with the ranks of $\mathbb{A}$, which, in turn, coincide with the ranks of the canonical characteristic set $\mathbb{C}$ and with the leading monomials of the reduced Gröbner basis GB computed in Algorithm 1. Moreover, $\mathbb{A}'$ is algebraically autoreduced, hence $\mathbb{A}' = GB$. This implies that characteristic set $\mathbb{A}$ can be obtained from the canonical characteristic set $\mathbb{C}$ through multiplying its elements by polynomials from $k[N]$.

The next two propositions demonstrate that canonical characteristic sets are “minimal” in a certain sense.

Proposition 4 *Let $\mathbb{C} = C_1, \dots, C_p$ be the canonical characteristic set of a characterizable differential ideal I . Let $\mathbb{B} = B_1, \dots, B_p$ be any characteristic*

set of the ideal I such that the initials of $\mathbb{B}$ depend only on the non-leaders N . Then,

$$I_{C_i} \leq_{\text{lex}} I_{B_i}$$

for all i , $1 \leq i \leq p$.

Proof By Corollary 1 all the other characteristic sets $\mathbb{B}$ with the initials from $k[N]$ can be obtained from $\mathbb{C}$ by multiplying its elements by polynomials from $k[N]$. The result follows immediately from this.

Proposition 5 Let $\mathbb{C} = C_1, \dots, C_p$ be the canonical characteristic set of a characterizable differential ideal I . Let v be a differential variable appearing in some C_i , $1 \leq i \leq p$. Then,

$$\frac{\partial C_i}{\partial v} \notin I.$$

Proof Suppose that $\frac{\partial C_i}{\partial v} \in I$. Then v appears effectively in the initial I_{C_i} .

Indeed, suppose that v is not in I_{C_i} , then $\frac{\partial C_i}{\partial v}$ is not reducible w.r.t. $\mathbb{C}$.

This contradicts the fact that $\mathbb{C}$ is a characteristic set of I and $\frac{\partial C_i}{\partial v} \in I$.

Now, since v appears effectively in I_{C_i} , the set

$$\mathbb{C}' = \mathbb{C} \setminus \{C_i\} \cup \left\{ \frac{\partial C_i}{\partial v} \right\}$$

is autoreduced and has the same rank as $\mathbb{C}$, hence $\mathbb{C}'$ is a characteristic set of I . Moreover, the initial of $\frac{\partial C_i}{\partial v}$ is equal to $\frac{\partial I_{C_i}}{\partial v}$, hence it does not depend on the leaders of $\mathbb{C}$. Yet $\frac{\partial C_i}{\partial v}$ is not a multiple of C_i , which contradicts Corollary 1.

Remark 1 Proposition 5 will be extremely important for our study of the bound on the orders of the elements of characteristic set. Section 4 will tell about this in detail.

3.3 Another algorithm for computing canonical characteristic sets

Let a differential ranking be fixed.

In (6, page 636) an algorithm **Invert** for inverting polynomials w.r.t a characteristic set is presented. Its input consists of a polynomial f and a characteristic set $\mathbb{C}$ of a characterizable ideal $(\mathbb{C}) : H_{\mathbb{C}}^{\infty}$. Let L and N be the sets of leaders and non-leaders of $\mathbb{C}$, respectively. Then, the output of the algorithm is:

- ‘yes’ and the inverse polynomial $g \in k[N][L]$ such that $fg = 1 \pmod{(\mathbb{C})}$ in the ring $k(N)[L]$, if f is invertible w.r.t. $\mathbb{C}$;
- ‘no’, otherwise.

In the following algorithm while inverting initials we always get the answer ‘yes’, so we just use the remaining (polynomial) part of its output. Let $\mathbb{C} = C_1, \dots, C_p$ be an autoreduced set. For each i , $1 \leq i \leq p$, denote $\mathbb{C}(i) = C_1, \dots, C_i$.

Algorithm 2 Canonical Characteristic Set

INPUT: a characteristic set $\mathbb{C} = C_1, \dots, C_p$ of a characterizable differential ideal $I = [\mathbb{C}] : H_{\mathbb{C}}^{\infty}$ in $k\{y_1, \dots, y_l\} = k\{Y\}$.

OUTPUT: the canonical characteristic set of I .

- Let $C_i = I_{C_i} u_{C_i}^{n_i} + a_{1,i} u_{C_i}^{n_i-1} + \dots + a_{n_i,i}$, $1 \leq i \leq p$.
- $L := \text{Leaders}(\mathbb{C})$.
- $N := \Theta Y \setminus \Theta L$.
- for i from 2 to p do
 - $I'_i := \text{Invert}(I_{C_i}, \mathbb{C}(i-1))$.
 - $C_i := I'_i C_i$.
 - $C_i := \text{Pseudo_Remainder}(C_i)$ w.r.t. $\mathbb{C}(i-1)$.
- for i from 1 to p do
 - $C_i := C_i / \gcd(I_{C_i}, a_{1,i}, \dots, a_{n_i,i})$ in $k[N][L]$.
 - divide C_i by its leading coefficient from k
- Return $\mathbb{C}$.

Remark 2 Note that the coefficients $a_{i,j}$ at the end of the algorithm are the new coefficients of the new C_i .

Lemma 2 Algorithm 2 is correct, i.e., its output is the canonical characteristic set of I .

Proof First, note that after each iteration of the first *for*-loop the set $\mathbb{C}$ is still a characteristic set of the ideal I . Indeed, no C_i disappears during those reductions, because the initials I_{C_i} are always invertible in our situation.

The fact that the initials of C_i do not depend on leaders can be proved by induction on i . For $i = 1$ this is the case, since C_1 has the lowest rank in the characteristic set. Assume that the initials of the polynomials in $\mathbb{C}(i-1)$ do not depend on leaders. Consider the initial of C_i , $I''_i = I_{C_i} I'_i$, after multiplication by I'_i . We have $I''_i - 1 \in (\mathbb{C}(i-1))$ in $k(N)[L]$. During the computation of the pseudo-remainder of C_i w.r.t. $\mathbb{C}(i-1)$, the initial of I''_i may be pseudoreduced by some polynomials from $\mathbb{C}(i-1)$ or multiplied by their initials, which by inductive assumption belong to $k[N]$. Hence, if I'''_i is the initial of C_i after the computation of the pseudo-remainder, we have $I'''_i - f \in (\mathbb{C}(i-1))$, where $f \in k[N]$. Given that I'''_i and f are reduced w.r.t. $\mathbb{C}(i-1)$, we obtain $I'''_i - f = 0$, i.e., $I'''_i \in k[N]$.

The remaining two conditions for the canonicity (see Definition 5) of the output of Algorithm 2 are ensured by the second *for*-loop.

We now know how to compute canonical characteristic sets of characterizable differential ideals from any characteristic set characterizing the ideal. The canonical characteristic set is unique and has good properties of minimality. The next section is devoted to establishing facts about the bounds for characteristic sets. First, we do this for prime differential ideals (Theorem 6).

Then, Corollary 2 gives us a generalization of this result to characterizable ideals. Finally, in Section 5 we apply these results to canonical characteristic sets.

4 Bounds for the orders of characteristic sets

4.1 Preparation

Let $R = k\{y_1, \dots, y_l\}$ with $\Delta = \{\delta\}$. So, we are in the ordinary case. *Differential dimension* of a differential ideal I is the maximal number q such that $I \cap k\{y_{i_1}, \dots, y_{i_q}\} = \{0\}$. Recall that the order of a differential polynomial f is the maximal order of differential variables appearing effectively in f .

Fix any differential ranking. Let $\mathbb{A} = A_1, \dots, A_p$ be an autoreduced set. Define the order of $\mathbb{A}$ by the following equality: $\text{ord } \mathbb{A} = \text{ord } A_1 + \dots + \text{ord } A_p$. Let an *orderly* differential ranking be fixed. If $\mathbb{C}$ is a characteristic set of a *prime* differential ideal P then, by definition, the order of the ideal P equals $\text{ord } \mathbb{C}$.

Denote by $P(s)$ the set of elements of P whose order is less than or equal to s . The set $P(s)$ is a prime algebraic ideal in the corresponding polynomial ring. As it is proved in (17, II.12, Theorem 6) or (18, Theorems 5.4.1, 5.4.4) the dimension of $P(s)$ is a polynomial in s for $s \geq h = \text{ord } P$.

More precisely, $\dim P(s) = q(s + 1) + \text{ord } P$, where q is the differential dimension of the ideal P . Moreover, $q = l - p$, where p is the number of elements of a characteristic set of the ideal P w.r.t. any orderly ranking. Thus, the numbers $\text{ord } P$ and p do not depend on the choice of an orderly ranking.

We are going to define the order of a characterizable differential ideal and we should be very careful because of the following example.

Example 1 Consider the radical differential ideal $\{x(x + y')\} = I$ characterizable w.r.t. the elimination ranking $x >_{el} y$. While $I = [x] \cap [x + y']$ and the leaders of x and $x + y'$ w.r.t. the ranking are the same the orders of the components are different. This is because the ideal I is not characterizable w.r.t. any orderly ranking.

Hence, we give the following definition.

Definition 6 For a characterizable differential ideal $I = \bigcap_{i=1}^n P_i$, where P_i are minimal differential prime components of I , define

$$\text{ord } I = \max_{1 \leq i \leq n} \text{ord } P_i.$$

Remark 3 The theory of differential dimensional polynomials is due to Kolchin (17). Carrà Ferro and Sit continued to develop this subject (23; 8; 9). Many of the results concerning differential dimension polynomials are summarized in (18). The latter book also presents many algorithms for computing these polynomials.

Lemma 3 (22, Proposition 17) *Consider a prime differential ideal P of differential dimension q and order h . For every subset $\{y_{i_1}, \dots, y_{i_{q+1}}\}$ of $\{y_1, \dots, y_l\}$, the ideal P contains a differential polynomial in the indeterminates $\{y_{i_1}, \dots, y_{i_{q+1}}\}$ of order less than or equal to h .*

A characteristic set of a prime differential ideal is not unique. For example, consider the ideal $[x] \in k\{x, y\}$ and the elimination ranking with $x > y$. Then the set $y^{(n)}x$ is a characteristic set of the ideal $[x]$ for any $n \geq 0$. Hence, if we do not impose additional restrictions, we will not be able to obtain a bound on the order of characteristic sets of a prime differential ideal.

In order to avoid this problem, in (22) Sadik introduced the concept of *irreducible* characteristic set and proved its existence (22, Lemma 19) for any prime differential ideal.

Definition 7 A characteristic set of a prime ideal is called *irreducible in Sadik's sense* if

1. C_1 is an irreducible polynomial in $k\{y_1, \dots, y_l\}$,
2. each C_{i+1} is irreducible in the ring

$$R_i = \text{Quot}(k[V_i] / (C_1, \dots, C_i) : I_i^\infty)[U_i],$$

where

- V_i is the set of all variables appearing in the polynomials $C_1, \dots, C_i$,
- I_i^∞ is the multiplicative system generated by the initials of the polynomials $C_1, \dots, C_i$,
- U_i is the set of variables from C_{i+1} that are not in V_i .

The following result allows us to find a characteristic set of a prime differential ideal with good bounds on the orders of its elements w.r.t. *any* differential ranking.

We formulate the following result (Lemma 4) in the way we are going to use it. One can conclude from its proof that this is nothing else as: *a characteristic set which is irreducible in Sadik's sense satisfies the second condition of Lemma 4.*

Lemma 4 *A prime differential ideal P in $k\{y_1, \dots, y_l\}$ admits a characteristic set $\mathbb{A} = A_1, \dots, A_p$ with the following properties:*

1. *it is irreducible in Sadik's sense;*
2. *let $y_t^{(s)}$ be a differential variable appearing in $\mathbb{A}$. Assume also that $y_t^{(s)}$ does not appear in $A_1, \dots, A_{i-1}$ but does appear in A_i . Then*

$$S_{i,t} = \frac{\partial A_i}{\partial y_t^{(s)}} \notin P.$$

Proof Suppose that the second condition is failed for a characteristic set $A_1, \dots, A_p$ irreducible in Sadik's sense, which exists by (22, Lemma 19). Let z be a variable that does not appear in $\mathbb{A} = A_1, \dots, A_{i-1}$ but does appear in A_i and satisfies $\frac{\partial A_i}{\partial z} \in P$. Take the canonical characteristic set $C_1, \dots, C_p$ of the ideal P .

Consider the unique factorization domain R_{i-1} constructed from $A_1, \dots, A_{i-1}$ in Definition 7. The variable z is an indeterminate in this ring. Since $\mathbb{A}$ is irreducible, the polynomial A_i is irreducible in R_{i-1} . The polynomial C_i is reducible to zero w.r.t. $\mathbb{A}$. Hence C_i is reducible to zero w.r.t. A_i in R_{i-1} , since $A_1, \dots, A_{i-1}$ is a characteristic set of the prime ideal $(A_1, \dots, A_{i-1}) : I_{i-1}^\infty$. Then, there exists a number k and a polynomial $D_i \in R_{i-1}$ such that $I_{A_i}^k C_i = D_i A_i$. Since $D_i A_i$ is divisible by C_i and A_i is irreducible, we have $C_i = E_i A_i$ for some factor E_i of D_i . Thus, the polynomial C_i must contain the variable z . Since the polynomial $f = I_{C_i} A_i - I_{A_i} C_i \in P$ is reduced w.r.t. A_i , we have

$$f \in J := (A_1, \dots, A_{i-1}) : I_{i-1}^\infty,$$

where I_{i-1} denotes the multiplicative set generated by the initials $I_{A_1}, \dots, I_{A_{i-1}}$.

Since z does not appear in $A_1, \dots, A_{i-1}$, there exist generators of the ideal J not containing this variable. Hence $\frac{\partial f}{\partial z} \in P$. On the other hand,

$$\frac{\partial f}{\partial z} = \frac{\partial A_i}{\partial z} I_{C_i} - \frac{\partial C_i}{\partial z} I_{A_i} + \frac{\partial I_{C_i}}{\partial z} A_i - \frac{\partial I_{A_i}}{\partial z} C_i \equiv \frac{\partial A_i}{\partial z} I_{C_i} - \frac{\partial C_i}{\partial z} I_{A_i} \pmod{P}.$$

Thus, from $\frac{\partial A_i}{\partial z} \in P$ and Proposition 5, we have $I_{A_i} \in P$. But the initials of a characteristic set of a prime ideal cannot belong to it. Contradiction.

4.2 Bound for prime differential ideals

Theorem 6 *Let P be a prime differential ideal of order h in $k\{y_1, \dots, y_l\}$ and $>$ be a differential ranking (not necessarily orderly!). Then there exists a characteristic set $\mathbb{C} = C_1, \dots, C_n$ of the ideal P w.r.t. the ranking $>$ such that the order in y_t of each C_i does not exceed h for all $1 \leq t \leq l$.*

Proof For a characteristic set $\mathbb{C}$ of P denote the set

$$\{y_k \mid \theta y_k \text{ is not a leader of any } C_j, 1 \leq j \leq n, \theta \in \Theta\}$$

by $\mathfrak{N}$. If for some $\theta \in \Theta$ and $t, 1 \leq t \leq l$, the variable θy_t is the leader of some C_j then we will show that $\text{ord}(C_q, y_t) \leq h$ for all $1 \leq q \leq n$ using Lemma 3. Indeed, since $\mathbb{C}$ is autoreduced, we have

$$\text{ord}(C_q, y_t) \leq \text{ord } \theta, \tag{1}$$

for all $q, 1 \leq q \leq n$. Since $\dim P = \#\mathfrak{N}$, by Lemma 3 there exists a polynomial

$$0 \neq f \in k\{y_t, \mathfrak{N}\} \cap P$$

of order not greater than h . This polynomial depends only on non-leaders $\mathfrak{N}$ and the leading variable y_t . Moreover, f is reducible to zero w.r.t. $\mathbb{C}$. Hence,

$$\text{ord } \theta = \text{ord}(C_j, y_t) \leq \text{ord}(f, y_t) \leq h. \tag{2}$$

The inequalities (1) and (2) give us

$$\text{ord}(C_q, y_t) \leq h$$

for all q , $1 \leq q \leq n$.

Now let $y_t \in \mathfrak{N}$ and $\mathbb{C}$ be a characteristic set which Lemma 4 provides to us. Let also y_{C_j} denote the differential indeterminate such that θy_{C_j} is the leader of C_j for some $\theta \in \Theta$, that is, y_{C_j} is the leading variable of C_j . The main idea is to reduce the polynomial of the *smallest order with respect to* y_{C_j}

$$f_j \in k\{y_{C_j}, \mathfrak{N}\} \cap P$$

given by Lemma 3 w.r.t. $\mathbb{C}$. Let $u = y_{C_j}^{(r)}$ be the derivative of y_{C_j} of the highest order in f_j . If we represent f_j as a univariate polynomial in u then denote by I_{f_j} its leading coefficient. Notice that I_{f_j} does not have to be the initial of f_j w.r.t. our ranking, but we still use this notation for convenience. For instance, I_{f_j} would be the initial of f_j w.r.t. the elimination ranking $y_{C_j} > \mathfrak{N}$. We emphasize that

$$I_{f_j} \notin P.$$

Suppose that for some j , $1 \leq j \leq n$, we have

$$\text{ord}(C_j, y_t) > h. \quad (3)$$

Since f_j is reducible to zero w.r.t. $\mathbb{C}$ we must have

$$\text{ord}(f_j, y_{C_j}) \geq \text{ord}(C_j, y_{C_j}). \quad (4)$$

Denote by “arg max ord” the *set* of all elements which provide the maximum of the order. Consider

$$\tilde{\mathbb{C}} = \arg \max_{C_j \in \mathbb{C}} \text{ord}(C_j, y_t)$$

and then choose $C_i \in \tilde{\mathbb{C}}$ of the *lowest* possible rank. We can have many elements in $\tilde{\mathbb{C}}$. But we take the special one, C_i . Let $u_i = \theta_i y_i$ for some $\theta_i \in \Theta$ and u_i be the leader of C_i for simplicity. From (3) and (4) we have

$$s = \text{ord}(C_i, y_t) > h \quad (5)$$

and

$$r_f = \text{ord}(f_i, y_i) \geq \text{ord}(C_i, y_i) = r_C,$$

where

$$f_i = f_i(y_i, \mathfrak{N}) = I_{f_i} \left(y_i^{(r_f)} \right)^{n_f} + a_1 \left(y_i^{(r_f)} \right)^{n_f-1} + \dots + a_{n_f}.$$

Let us reduce each term (coefficients a_j , “initial” I_{f_i} and its “leader” $y_i^{(r_f)}$) of f_i first by C_i . We need to differentiate C_i q times and get the remainder $\tilde{f}$, where $0 \leq q \leq r_f - r_C$. Remember that f_i depends only on $y_i, \mathfrak{N}$, and their derivatives. By reduction here we mean the following. Any proper derivative θ of C_i is linear in θu_i and its initial is equal to the separant of C_i . We simply

multiply f_i by a sufficient power (say, n_f) of the separant and replace $y_i^{(r_f)}$ and the derivatives of y_i of lower order in f_i by the corresponding tails.

Hence, applying further steps of reduction to the terms of $\tilde{f}$ w.r.t. all C_j we need to differentiate them *less* than q times if $C_j \in \tilde{\mathbb{C}}$. Indeed, the fact that $C_i < C_j$, as C_i has the smallest rank in $\tilde{\mathbb{C}}$, implies

$$\text{ord}(C_i, y_{C_j}) < \text{ord}(C_j, y_{C_j}).$$

We need to differentiate them *not greater* than q times if $C_j \notin \tilde{\mathbb{C}}$. Indeed, the set $\mathbb{C}$ is autoreduced, so

$$\text{ord}(C_i, y_{C_j}) \leq \text{ord}(C_j, y_{C_j}).$$

In addition, the variables to reduce can come just from derivatives of variables from C_i .

In the case of $r_f = r_C$ we are in (22, Lemma 20) because of our choice of C_i and immediately get the inequality

$$\text{ord}(f_i, y_t) \geq \text{ord}(C_i, y_t). \quad (6)$$

Since $\text{ord}(f_i, y_t) \leq h$, the inequality (6) contradicts to inequality (5).

Consider the other case of $r_f > r_C$. Here, after we reduce all leaders of $\mathbb{C}$ from f we get the polynomial depending effectively on $y_t^{(s+q)}$ and $s+q \geq s$. Its leading coefficient w.r.t. the variable $y_t^{(s+q)}$ is equal to

$$I_{C_1}^{i_1} \cdots I_{C_n}^{i_n} \cdot S_{C_1}^{j_1} \cdots S_{C_n}^{j_n} \cdot \tilde{I}_{f_i} \cdot \left(\frac{\partial C_i}{\partial y_t^{(s)}} \right)^{n_f}, \quad (7)$$

where $i_1, \dots, i_n, j_1, \dots, j_n \in \mathbb{Z}_{\geq 0}$ and $\tilde{I}_{f_i}$ is the remainder of I_{f_i} w.r.t. $\mathbb{C}$. Remember that P is a prime ideal. Hence,

$$I_{C_1}^{i_1} \cdots I_{C_n}^{i_n} \cdot S_{C_1}^{j_1} \cdots S_{C_n}^{j_n} \notin P, \quad (8)$$

because I_{C_j} and $S_{C_j} \notin P$ for all j , $1 \leq j \leq n$. Moreover, $P = [\mathbb{C}] : H_{\mathbb{C}}^{\infty}$ and $\mathbb{C}$ is a characteristic set of $[\mathbb{C}] : H_{\mathbb{C}}^{\infty}$. Also,

$$\tilde{I}_{f_i} \notin P, \quad (9)$$

because $I_{f_i} \notin P$ due to our choice of f_i . By the Rosenfeld lemma, the remainder of f_i we are computing belongs to the prime algebraic ideal $(\mathbb{C}) : H_{\mathbb{C}}^{\infty}$. Thus, according to Lemma 1, its leading coefficient given by (7) is reducible to zero w.r.t. $\mathbb{C}$. For a prime differential ideal the fact that an element is reducible to zero w.r.t. a characteristic set is nothing else the element belongs to the ideal. Using (8) and (9) we conclude that the polynomial $\frac{\partial C_i}{\partial y_t^{(s)}}$ belongs to P . Finally, this contradicts to Lemma 4.

Remark 4 Note that Theorem 6 is actually a generalization of Sadik's result (22, Theorem 24) that was proved just for elimination rankings. In the proof of Theorem 6 we construct the set $\tilde{\mathbb{C}}$ and choose a special element $C_i \in \tilde{\mathbb{C}}$. Sadik used induction here.

4.3 Characterizable ideals: main estimate for the bound

We do not need the ordinary case for the following result. Fix a ring of differential polynomials $k\{y_1, \dots, y_l\}$.

Theorem 7 *Suppose a function h from the set of prime differential ideals to the set $\mathbb{Z}_{\geq 0}$ is such that for any prime differential ideal P there exists its characteristic set $C_1, \dots, C_p$ with the property $\text{ord } C_i \leq h(P)$ for all i , $1 \leq i \leq p$. Then for any characterizable differential ideal I there exists its characteristic set $\mathbb{B} = B_1, \dots, B_k$ characterizing this ideal ($I = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$) such that*

$$\text{ord } B_i \leq \max_{1 \leq j \leq n} h(P_j) =: h(I)$$

for all i , $1 \leq i \leq k$, where the set of ideals $\{P_j \mid 1 \leq j \leq n\}$ is the minimal prime decomposition of I .

Proof Take the minimal prime decomposition $I = \bigcap_{j=1}^n P_j$ and choose a characteristic set $\mathbb{C}_j = C_{j,1}, \dots, C_{j,p_j} \subset P_j$ with $\text{ord } C_{j,i} \leq h(P_j) \leq h(I)$ for all i , $1 \leq i \leq p_j$, and j , $1 \leq j \leq n$. We have

$$I = \bigcap_{j=1}^n [\mathbb{C}_j] : H_{\mathbb{C}_j}^{\infty}.$$

Let $\mathbb{B}$ be any characteristic set of I characterizing this radical differential ideal, i.e., $I = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$, and L be the set of its leaders which is uniquely determined by I and does not depend on the choice of $\mathbb{B}$. Let N be the (infinite) set of all other variables from $k\{y_1, \dots, y_l\}$. From Theorem 3 we know that

$$J = (\mathbb{B}) : H_{\mathbb{B}}^{\infty} = \bigcap_{j=1}^n (\mathbb{C}_j) : H_{\mathbb{C}_j}^{\infty}.$$

in the ring $k[N, L]$ and $\mathbb{B}$ is an algebraic characteristic set of J which can be computed, e.g., from the reduced Gröbner basis G of the ideal J . We just need to notice that G can be computed from all $\mathbb{C}_j$ without involving extra variables from the set N . To conclude that $I = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$ we use (13, Lemmas 3.5, 3.9, and 6.1).

Let us switch to the *ordinary case* and see what corollaries Theorem 7 gives us.

Corollary 2 *In the ordinary case for a characterizable differential ideal I there exists a characteristic set $\mathbb{C} = C_1, \dots, C_p$ with the following properties:*

- $I = [\mathbb{C}] : H_{\mathbb{C}}^{\infty}$.
- $\text{ord } C_i \leq \text{ord } I$ (see Definition 6) for all i , $1 \leq i \leq p$.

Proof Follows from Theorem 6 and Theorem 7 setting $h(P) = \text{ord } P$.

5 Bound for the order of the canonical characteristic set

We need the ordinary case for the following assertions about bounds. In this theorem we also reprove the uniqueness of the canonical characteristic set of a characterizable differential ideal. Note that we need the ordinary case only for our bound but not for the uniqueness. Let some differential ranking be fixed.

Theorem 8 *Let $\mathbb{C} = C_1, \dots, C_p$ be the canonical characteristic set of a characterizable differential ideal I . The set $\mathbb{C}$ is uniquely determined and has the following bound*

$$\text{ord } C_i \leq \text{ord } I$$

for all $i, 1 \leq i \leq p$.

Proof Let $\mathbb{B}$ be any characteristic set of the ideal I with invertible initials and separants. Such a set characterizes I , i.e., we have $I = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$. Hence,

$$[\mathbb{C}] : H_{\mathbb{C}}^{\infty} = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}.$$

Let us move into the ring $k(N)[L]$. Both $\mathbb{C}$ and $\mathbb{B}$ are autoreduced sets of the same rank. Hence, they have the same leaders and the degrees of these leaders. Thus, all the elements of $\mathbb{B}$ are partially reduced w.r.t. $\mathbb{C}$. Then, $\mathbb{B} \subset (\mathbb{C}) : H_{\mathbb{C}}^{\infty} = (\mathbb{C})$ by Theorem 1. The latter equality follows from (13, Proposition 3.3 and Lemma 6.1)

The initials and separants of $\mathbb{B}$ are invertible. Hence, for any $h \in H_{\mathbb{B}}^{\infty}$ there exists $h' \in k[N][L]$ such that $hh' = 1 + f$, where $f \in (\mathbb{B})$. Let $a \in (\mathbb{B}) : H_{\mathbb{B}}^{\infty}$. So, there exists $h \in H_{\mathbb{B}}^{\infty}$ such that $ha \in (\mathbb{B})$. Hence, $hh'a = (1 + f)a = a + af \in (\mathbb{B})$ and $a \in (\mathbb{B})$.

Then, $(\mathbb{B}) : H_{\mathbb{B}}^{\infty} = (\mathbb{B}) \subset (\mathbb{C}) : H_{\mathbb{C}}^{\infty}$. In the same way, $(\mathbb{C}) : H_{\mathbb{C}}^{\infty} \subset (\mathbb{B}) : H_{\mathbb{B}}^{\infty}$. Thus,

$$(\mathbb{C}) : H_{\mathbb{C}}^{\infty} = (\mathbb{B}) : H_{\mathbb{B}}^{\infty}.$$

As a result, Algorithm 1 does give its answer independently of the choice of the input characteristic set of a fixed characterizable differential ideal.

Let us prove now the bound for the orders. Compute the canonical characteristic set of the ideal I using the result of Corollary 2. So, let $\mathbb{B} = B_1, \dots, B_p$ be a characteristic set given by Corollary 2. We have $\text{ord } B_i \leq \text{ord } P$ for all $i, 1 \leq i \leq p$.

No steps of Algorithm 1 involve differentiations and no new variable can appear in the output. Since the canonical characteristic set does not depend on the choice of input characteristic set of I , we have the bound for $\mathbb{C}$ we need.

6 Computation of the canonical characteristic set from generators

We do *not* assume the ordinary case now. Fix a differential ranking. The algorithm for computing a characteristic set of a prime differential ideal (represented by its generators as a radical differential ideal, $I = \{F\}$) is given in (2, Theorem 6). It simply

- takes the first component of its `Rosenfeld_Gröbner` decomposition (appeared in (2));
- computes reduced Gröbner basis of the correspondent algebraic ideal;
- applies algebraic pseudo-autoreduction to this basis, extracting a characteristic set of the ideal I .

Note that the above algorithm works only for prime differential ideals. The case of *characterizable* ideals specified by *sets of generators* as radical differential ideals is more tricky. The following Algorithm 3 computes the canonical characteristic set in this case (see Proposition 6 for the proof).

Remark 5 It is not known how to perform the inverse transformation between the two representations, i.e., how to compute a set of generators of a characterizable ideal given its canonical characteristic set.

Algorithm 3 Characteristic Set of a Characterizable Differential Ideal

INPUT: a finite set F of differential polynomials generating a characterizable differential ideal.

OUTPUT: the canonical characteristic set of $\{F\}$.

- Let $\mathfrak{C} = \text{Rosenfeld_Gröbner}(F)$ and $\mathfrak{C} = \mathbb{C}_1, \dots, \mathbb{C}_n$.
- Let $[\mathbb{C}_{i_j}] : H_{\mathbb{C}_{i_j}}^\infty$ be the components whose characteristic sets have the sets of leaders of the highest possible rank in $\mathfrak{C}$ and $1 \leq j \leq k$.
- Let $I' = \bigcap_{j=1}^k (\mathbb{C}_{i_j}) : H_{\mathbb{C}_{i_j}}^\infty$.
- $L := \text{Leaders}(\mathbb{C}_{i_1})$.
- $N := \Theta Y \setminus \Theta L$.
- $GB := \text{Reduced_Gröbner_Basis}(I')$ in $k(N)[L]$.
- $\mathbb{D} := \text{Clear_out_denominators}(GB)$ in $k(N)[L]$.
- divide each element of $\mathbb{D}$ by its leading coefficient from k .
- Return $\mathbb{D}$.

One can think that the property of a radical differential ideal to be characterizable can be checked in this way (by computing the canonical characteristic set). But this is not the case. Radical differential ideals having characteristic sets satisfying Definition 5 may not be characterizable. This is illustrated in Examples 4 and 5.

Remark 6 Algorithm `Rosenfeld_Gröbner` is presented in (2) and (3) and implemented in Maple.

Remark 7 Note that in the second line of the above algorithm it would not be sufficient to consider only the characterizable components having characteristic sets of the highest rank in $\mathfrak{C}$. Indeed, let $x > y > z$, and consider the following algebraic characterizable ideal and its decomposition into characterizable components:

$$I = (y^2 + z, x^3 + x^2y + xy - z) = (y^2 + z, x + y) \cap (y^2 + z, x^2 + y).$$

The characteristic sets of both components have the same set of leaders, $\{x, y\}$. The component of the highest rank is $(y^2 + z, x^2 + y)$ and, clearly, $I \neq (y^2 + z, x^2 + y)$.

Proposition 6 *Algorithm 3 computes the canonical characteristic set of the given characterizable differential ideal $\{F\}$.*

Proof Let $\mathbb{C}$ be the canonical characteristic set of the characterizable ideal $I = \{F\}$.

First, let us prove an auxiliary

Lemma 5 *Let P be a prime differential ideal with a characteristic set $\mathbb{A}$ whose set of leaders coincides with that of $\mathbb{C}$, where $\mathbb{C}$ is a characteristic set of $[\mathbb{C}] : H_{\mathbb{C}}^{\infty} = I$. Assume also that $I \subseteq P$. Then $(\mathbb{C}) : H_{\mathbb{C}}^{\infty} \subset (\mathbb{A}) : H_{\mathbb{A}}^{\infty}$.*

Proof Let $f \in (\mathbb{C}) : H_{\mathbb{C}}^{\infty}$. Then f is partially reduced w.r.t. $\mathbb{C}$. Since the leaders of $\mathbb{A}$ and $\mathbb{C}$ coincide, f is partially reduced w.r.t. $\mathbb{A}$. Since $f \in I$ and $I \subseteq P$, we have $f \in P$. Hence, by Rosenfeld's lemma (Theorem 1), $f \in (\mathbb{A}) : H_{\mathbb{A}}^{\infty}$.

Consider the prime decomposition $I = \bigcap P_i$, where P_i 's are the essential prime components of I . Let $\mathbb{A}_i$ be a characteristic set of P_i , then, according to Theorem 3, ideal $P'_i = (\mathbb{A}_i) : H_{\mathbb{A}_i}^{\infty}$ is a minimal prime component of the algebraic ideal $(\mathbb{C}) : H_{\mathbb{C}}^{\infty}$.

Consider also the essential prime decompositions $J_l = \bigcap Q_{lj}$ of the characteristic components $J_l = [\mathbb{C}_l] : H_{\mathbb{C}_l}^{\infty}$ of I . The intersection of these decompositions is a finite prime decomposition of I . According to (21, Section I.16), every essential prime component appears in every finite prime decomposition of the radical ideal I , which implies that every P_i can be found among Q_{lj} . Moreover, according to Theorem 2, the leaders of $\mathbb{A}_i$ coincide with the leaders of $\mathbb{C}$, hence P_i can be found among those Q_{lj} whose characteristic sets have leaders coinciding with the leaders of $\mathbb{C}$.

Applying Theorem 2 again, we obtain that P_i can be found among the essential prime components of those J_l whose characteristic sets $\mathbb{C}_l$ have leaders coinciding with the leaders of $\mathbb{C}$. Now, since for each l , $I \subseteq J_l$, the rank of the set of leaders of $\mathbb{C}_l$ is lower than or equal to the rank of the set of leaders of $\mathbb{C}$. Hence, P_i can be found among the essential prime components of those J_l , for which the set of leaders of $\mathbb{C}_l$ has the highest rank, i.e., among the essential prime components of $J_{i_1}, \dots, J_{i_k}$.

Thus, by Theorem 3, every minimal prime P'_i of the algebraic ideal $(\mathbb{C}) : H_{\mathbb{C}}^{\infty}$ can be found among the minimal primes of the algebraic ideals $(\mathbb{C}_{i_1}) : H_{\mathbb{C}_{i_1}}^{\infty}, \dots, (\mathbb{C}_{i_k}) : H_{\mathbb{C}_{i_k}}^{\infty}$, and we obtain

$$(\mathbb{C}) : H_{\mathbb{C}}^{\infty} \supseteq \bigcap_{j=1}^k (\mathbb{C}_{i_j}) : H_{\mathbb{C}_{i_j}}^{\infty} = I'.$$

The inverse inclusion follows from the above Lemma 5. Hence, $I' = (\mathbb{C}) : H_{\mathbb{C}}^{\infty}$, and the canonical characteristic set $\mathbb{D}$ of I' computed by the above algorithm coincides with that of $(\mathbb{C}) : H_{\mathbb{C}}^{\infty}$ and of I .

7 Canonical characteristic sets of prime differential ideals

Prime differential ideals are characterizable. Can we say more about their canonical characteristic sets? Theorem 6 is based on finding a characteristic set of a prime differential ideal satisfying two properties:

1. Separants are not in the ideal;
2. Sadik's property of irreducibility.

Such a characteristic set exists (see Lemma 4). Moreover, the orders of its elements are bounded by the order of the ideal. Applying Algorithm 2, we get a canonical characteristic set certainly satisfying the same bound on the orders.

So, it is natural to ask whether this uniquely determined canonical characteristic set satisfies the properties 1–2. It turns out that the answer is only partially positive! The first property holds for a bigger class of ideals, namely, characterizable ones. This is shown in Proposition 5. The second property is not necessarily true. This is shown in Example 2.

Example 2 Consider the ideal $I = \{x^2 - t, (zx + 1)y + 1\} \subset k\{x, t, z, y\}$ and any differential ranking such that $y > z > x > t$. The set $x^2 - t, (zx + 1)y + 1$ is a characteristic set of I and it is irreducible in Sadik's sense.

Nevertheless, the canonical characteristic set of I , which is equal to $x^2 - t, (z^2t - 1)y + zx - 1$ is not irreducible by Sadik because

$$\begin{aligned} (z^2t - 1)y + zx - 1 &= (z^2x^2 - 1)y + zx - 1 = \\ &= (zx - 1)(zx + 1)y + (zx - 1) = \\ &= (zx - 1)((zx + 1)y + 1) \end{aligned}$$

in the polynomial ring $\text{Quot}(k[x, t]/(x^2 - t))[y, z]$.

Remark 8 Example 2 also shows that Proposition 4 is not true if we omit the condition that the initials depend only on non-leaders.

In conclusion, we note that the object we computed, i.e. the canonical characteristic set of a prime differential ideal, is not just unique but also has additional natural properties such as a low differential order of its elements, as well as other properties showing that the choice of requirements for the canonical characteristic set is not arbitrary. The importance of a characteristic set having these properties is, again, shown in Theorem 6.

8 Testing equality of characterizable ideals

As was mentioned in the Introduction, the canonical characteristic set trivially allows to check equality of two characterizable ideals: two characterizable ideals are equal if and only if their canonical characteristic sets coincide. However, one can also check the equality of characterizable ideals specified by any characterizing sets using the following criterion.

Theorem 9 *Let $\mathbb{A}$ and $\mathbb{B}$ be characteristic sets of characterizable ideals $I = [\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ and $J = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$, respectively. Then $I = J$ iff $\mathbb{A} \subset J$ and $\mathbb{B} \subset I$.*

Proof Assume that $\mathbb{A} \subset J$, $\mathbb{B} \subset I$. Since $\mathbb{A}$ is a characteristic set of I , i.e., an autoreduced subset of I of the least rank, and since $\mathbb{B}$ is an autoreduced subset of I , we have $\text{rank } \mathbb{A} \leq \text{rank } \mathbb{B}$. Symmetrically, $\text{rank } \mathbb{B} \leq \text{rank } \mathbb{A}$. Thus, the ranks of $\mathbb{A}$ and $\mathbb{B}$ are equal.

We show now that $I = J$. It is sufficient to demonstrate that $I \subset J$, since the proof of the inverse inclusion is symmetric. Moreover, since J is characterized by $\mathbb{B}$, it is sufficient to show that for all $f \in I$, f can be reduced to 0 w.r.t. $\mathbb{B}$. Let $f \in I$, and let f' be the differential remainder of f w.r.t. $\mathbb{B}$. Then, since $\mathbb{B} \subset I$, $f' \in I$. But f' is not reducible w.r.t. $\mathbb{B}$ and, given that $\text{rank}_{\leq} \mathbb{A} = \text{rank}_{\leq} \mathbb{B}$, f' is also not reducible w.r.t. $\mathbb{A}$. Hence, $f' = 0$.

The converse implication, that $I = J$ implies inclusions $\mathbb{A} \subset J$ and $\mathbb{B} \subset I$, is straightforward.

Proposition 7 *If $\mathbb{A}$ is a characteristic set of a non-trivial characterizable differential ideal $[\mathbb{A}] : H_{\mathbb{A}}^{\infty} = I$ then $H_{\mathbb{A}} \notin I$.*

Proof Assume that $H_{\mathbb{A}} \in I$. Then there exists $h \in H_{\mathbb{A}}^{\infty}$ such that $h \cdot H_{\mathbb{A}} \in [\mathbb{A}]$. Hence, for $h_1 = h \cdot H_{\mathbb{A}} \in H_{\mathbb{A}}^{\infty}$ we have $1 \cdot h_1 \in [\mathbb{A}]$, which implies that I contains 1.

Corollary 3 *The criterion given by Kolchin: “two prime differential ideals $I = [\mathbb{A}] : H_{\mathbb{A}}^{\infty}$ and $J = [\mathbb{B}] : H_{\mathbb{B}}^{\infty}$ given by their characteristic sets $\mathbb{A}$ and $\mathbb{B}$ coincide iff*

1. $\mathbb{A} \subset J$,
2. $\mathbb{B} \subset I$,
3. $H_{\mathbb{A}} \notin J$,
4. $H_{\mathbb{B}} \notin I$;

holds in the case of characterizable differential ideals.

Proof Necessity can be derived from Proposition 7. Sufficiency follows from Theorem 9.

9 Examples

We illustrate how Algorithm 2 works.

Example 3 Consider again the ideal $I = \{x^2 - t, (zx + 1)y + 1\} \subset k\{x, t, z, y\}$ and any differential ranking such that $y > z > x > t$. The set $x^2 - t, (zx + 1)y + 1$ is a characteristic set of I . According to algorithm `Invert` we introduce a new variable w and compute the reduced Gröbner basis GB of the ideal $(x^2 - t, w - (zx + 1))$ w.r.t. the lexicographic ordering with $x > w > z > t$.

We have

$$GB = w^2 - 2w - z^2t + 1, zx + 1 - w, xw - x - zt, x^2 - t$$

and

$$GB \cap k[w, z, t] = w^2 - 2w - z^2t + 1 = P(w).$$

Substituting $w = 0$ we get $P(0) = 1 - z^2t \neq 0$. Hence, $zx + 1$ is invertible and

$$(zx + 1)(zx + 1 - 2) \equiv (zx + 1)^2 - 2(zx + 1) \equiv z^2t - 1 \pmod{(x^2 - t)}.$$

Take

$$(zx + 1 - 2)((zx + 1)y + 1) \equiv (z^2t - 1)y + zx - 1 \pmod{(x^2 - t)}.$$

So, the canonical characteristic set is equal to

$$x^2 - t, (z^2t - 1)y + zx - 1.$$

We know that any characterizable ideal has the canonical characteristic set. Is the converse true? If a radical ideal I has a characteristic set satisfying the conditions of Definition 5 this does not imply that the ideal I is characterizable! If we involve differentiations that the most common example in constructive differential algebra comes into the play:

Example 4 Consider the ring of differential polynomials $k\{y\}$ and the radical differential ideal

$$I := \{y'^2 + y\} = [y'^2 + y] : (y')^\infty \cap [y],$$

which is not characterizable, but its characteristic set $y'^2 + y$ satisfies all the conditions of Definition 5.

In the case of zero dimensional radical algebraic ideals the converse is true. More precisely, from Lemma (13, Lemma 3.5) it follows that if a zero dimensional radical ideal has the canonical characteristic set then this ideal is characterizable. This is not true in non-zero dimensional cases.

Example 5 Consider the polynomial ring $k[x, y, z, t]$, the ranking $y > x > z > t$, and the radical ideal

$$I = (zx + t, zy + t) = (zx + t, zy + t) : z^\infty \cap (z, t) = (zx + t, x - y) \cap (z, t).$$

One cannot exclude the second component (z, t) from this decomposition. So, it is minimal and the ideal I is not characterizable by (19, Theorem 3) (see also (20)). Nevertheless, its characteristic set $zx + t, zy + t$ w.r.t. the ranking $y > x > z > t$ is canonical.

10 Conclusions

The summary of results from (3; 4; 13; 14; 15) and the new results obtained in this paper suggest that the canonical characteristic set yields a convenient representation of a characterizable differential ideal: its non-algorithmic definition is simple and transparent, it allows to solve algorithmic problems such as ideal membership, it satisfies several natural properties, including the *bound on the orders* of its elements, and there exist efficient algorithms that convert other representations of a characterizable ideal (by a regular system or by any other characterizing set) into the canonical one. Moreover, one can compute the canonical characteristic set of a characterizable differential ideal, if the latter is specified either by its *set of generators* as a radical differential ideal, or by its (possibly redundant) characteristic decomposition.

Acknowledgements We are highly grateful to Michael F. Singer for suggesting to us the directions of exploring the subject of this paper. We thank Evelyne Hubert for the idea that has lead to the present definition and proof of uniqueness of a canonical differential characteristic set, for useful references, and for a productive discussion. We are thankful to Evgeniy V. Pankratiev for helpful comments and support, to William Y. Sit and Alexey Zobnin for important discussions, and also thank Alexey Zobnin for extensive comments on the draft of this paper. We appreciate suggestions of the referees very much.
